

- Explain the difference between the == operator and the === operator.
  - The == operator allow for type coercion, while the === operator does not.
- Explain what a closure is. (Note that JavaScript programs use closures very often)
  - Closure is passing a local binding to an enclosing scope.  
But it is described as referencing that binding in the enclosing scope
- Explain what higher order functions are.
  - Functions that take functions as arguments or return functions
- Explain what a query selector is and give an example line of JavaScript that uses a query selector.
  - The queryselector method returns the first element that matches the css selector. This makes it easy to navigate to a certain part of a html page.
  - Example:  
<h3>A h3 element</h3>  
  
document.querySelector("h3").style.backgroundColor = "red";
